

Deriving the Work Energy Theorem

David Awad

This is a small synopsis on the derivation of the work energy theorem!

The key step is to convert the calculus definition for acceleration into an expression that is a derivative of x .

$$a = \frac{dv}{dt} = \frac{dv}{ds} \frac{ds}{dt} = v \frac{dv}{ds}$$

We start with Newton's second law of motion, which states that the sum of all forces acting on a object are equal to a resultant force that is the object's mass times the objects acceleration.

$$\sum \vec{F} = ma$$

$$\sum \vec{F} = mv \frac{dv}{ds}$$

The integral of the force irrespective of position, is the definition of work

$$W = \int_{s_i}^{s_f} \sum \vec{F} ds$$

$$W = \int_{s_i}^{s_f} ma ds$$

Now we can substitute using our identity for acceleration.

$$a = v \frac{dv}{ds}$$

$$W = \int_{s_i}^{s_f} mv \frac{dv}{ds} ds$$

$$W = \int_{s_i}^{s_f} mv \frac{dv}{ds} ds$$

$$W = \int_{v_i}^{v_f} mv dv$$

$$W = \frac{1}{2} s^2 \Big|_{v_i}^{v_f}$$

And so we end up with a function for work that's completely irrespective of position!

$$W = \frac{1}{2} m v_f^2 - \frac{1}{2} m v_i^2$$
